ABSTRACT

Large Deflection Analysis of Composite Beams

Sai Manohari Kancharla

A beam made of composite material undergoing large deflections is analyzed based on a higher-order shear deformation theory. Composite materials offer several advantages over conventional materials in the form of improved strength to weight ratio, high impact strength, corrosion resistance, and design flexibility. The Euler-Bernoulli beam theory is valid only for small deflections and may be too restrictive in a number of applications. The formulation of the large deflection analysis of composite beams is carried out using the principle of virtual work. The spatial discretization is done using an $h$-$p$ version finite element method. The nonlinear large deflection equations are solved using an iterative process. Results are presented in the form of deflections as a function of position.
Acknowledgements

I would like to sincerely thank my advisor, Dr. Nithi T. Sivaneri, for his advising and teaching right from the beginning of my M.S. program. Thought out my research, he immensely supported me with patience, care and regard. In this journey under him, I feel I’ve learnt a quite lot in understanding the problem, improving problem solving skills and exploring new methods to solve a problem.

I would also like to thank Dr. Ever J. Barbero, for his constant support and encouragement during my research, graduate technical presentations and industrial visits, Dr. Terence D. Musho, for being my research committee member and rendering his support during my tough times. Also, I would like to extend my sincere regards to Dr. Victor H. Mucino and all the non-teaching staff of department of Mechanical Engineering for their timely support.

I’m fortunate to have friends like Anveeksh, Ranjith who gave a lot of moral support and confidence during my tough phases of life at WVU. From bottom of my heart, I’m indebted to my parents, Hari Babu and Lakshmi Rani and my brother Sai Krishna for their love and strong support at all the times. Finally, I sincerely thank the Almighty for providing all these and being with me all the time.

1 INTRODUCTION

1.1 Background

Large deflection of beams has vital applications in aircraft, aerospace vehicles, and heavy machinery. With the advent in new composite materials, many parts that require improved strength with lesser weight have been dominating the industry demands. In pursuit of such materials, this research is entitled to develop a theory to efficiently test the capability of a composite beam undergoing large deflection, greater than or equal to one tenth the height of beam, due to static loading.

1.2 Composite beams

A beam is generally considered a one-dimensional structure as its length is large when compared to its height and width. Composite materials are classified into laminated composites, fibrous composites, and particulate composites. Laminated composites are usually treated as plate elements. This is because composites have their planar dimensions comparatively larger than the thickness. Therefore, to study the behavior of composites, laminate plate theories were developed. When the width of the plate is small compared to the length it is treated as a beam.

1.3 Problem Statement or Need for Present Research

The Euler Bernoulli beam bending moment equation is stated as below

\[ M = -EI \frac{d^2w}{dx^2} \]  \hspace{1cm} (1.1)

where, \( M \) is the bending moment, \( EI \) is the flexural rigidity and \( \frac{d^2w}{dx^2} \) is the curvature of the deflected longitudinal axis.

Eq. (1.1) does not hold good for analyzing large scale deflections [Howell and Midha(1995)] many theories are proposed to analyze the large deflections of an isotropic beam. Linear laminate plate theory is shown to be inadequate for analysis of asymmetric composite laminate, even in small deflection range [Sun and Chin (1998)]. Some researchers have analyzed large deflection of composite beams using the First order Shear Deformation Theory (FSDT). The FSDT uses a shear correction factor, which is only an approximation. Therefore, a higher-order theory that could provide a better solution can may be used to formulate the finite element model. In the present research, theory has been developed to analyze the nonlinear
behavior of a composite beam under given loading by solving finite element equations the formulation is based on the Higher order Shear Deformation Theory (HSDT).

1.4 LITERATURE REVIEW

1.4.1 Large deflections of isotropic beams

Different frameworks have been developed by several research groups over the years. The numerical results by Mattiasson (1980) involved the evaluation of elliptical integrals to obtain a nonlinear response to large loads.

Bisshopp and Drucker (1945) have studied the large deflection of cantilever beams. They Derive an analytical solution for a cantilever beam subjected to a concentrated vertical load at the free end. The derivation is based on the fundamental Euler-Bernoulli beam which assumes that the curvature is proportional to the bending moment. The results are in agreement with the experimental observations.

Mattiasson (1980) have described a numerical technique for evaluating the elliptic integrals solutions of some large-deflection beam and frame problems. They present highly-accurate results in tabular form.

Howell and Midha (1995) have developed a simple method for approximating the deflection path of end-loaded, large-deflection cantilever beams. The approximation are accurate to within 0.5 percent of closed form elliptic integral solutions.

1.4.2 Large deflections of composite beams

Non-linear analysis of composite beams undergoing large scale deflections are not numerous in the literature.

Sun and Chin (1988) have studied the deflection of asymmetric cross-ply composite laminates and conclude that linear laminate plate theory is in adequate to analyze asymmetric composite laminates with strong extension-bending coupling, and that large-deflection theory should be used even in the small-deflection range. For cylindrical bending problems, they provide a simple procedure by reducing the governing equation to linear differential equation with nonlinear boundary conditions. The von Karman plate-theory is used to analyze composite laminates under in-plane and transverse loadings.

Stemple and Lee (1989) developed a finite element model accounting for the warping effect of composite beams undergoing large deflection or finite rotation. The formulation is used to model combined torsional and extensional behavior of composite helicopter rotor blades. The strain is assumed to vary linearly through the wall thickness. The total Lagrangian description is
adopted for the formulation and the Newton-Raphson method is applied to solve the nonlinear equilibrium equations resulting from the finite element approximation.

Koo and Kwak (1993) propose a finite element method based on the FSDT for analyzing the deflections of composite frames. Deflections are separately interpolated for bending and shear using cubic and linear functions, respectively. A projected matrix was constructed using equilibrium equation, force and displacement relation. Error due to projection approaches zero with the increase in number of elements. In this method, shear locking has not occurred.

Vo and Lee (2010) analyze geometric nonlinearity of thin walled composite beams with arbitrary lay-ups under various types of loads. The nonlinear finite element equations are solved using the Newton-Raphson method. The formulation is based on FSDT. They develop a displacement-based one-dimensional finite element model that accounts for geometric nonlinearity in the von Karman sense to solve the problem. Numerical results are obtained for a beam under a vertical load.

1.4.3 Reduction of plate theories to beam

Chandrasekaran (2000) has studied the behavior of moving laminate composite beams using finite element method based on variational principle. The formulation is carried out with the CLPT as well as FSDT. He presents a systematic way to reduce plate theories to beams. Newmark’s time integration method is used to find the response of the moving beam. The displacement response is studied for both symmetric and unsymmetric laminates.

Sivaneri and Vennam (2010) have presented a systematic formulation to reduce plate equations to beams. They study the hygrothermal effects on free-vibration characteristics of rotating composite beams using the finite element analysis based on the variational principle. The formulation is based on FSDT.

Sivaneri and Nagappan (2012) have analyzed the dynamic behavior of axially-moving composite laminated beams based on HSDT. A finite element formulation based on the variational principle is used. They employ a systematic approach to reduce plate equations to beams. Results are presented in the form of time history of tip deflections. They compare the performance of HSDT model with that of CLPT and FSDT.

Polina and Sivaneri (2014) use a consistent formulation to reduce composite plate equations to beams in the study of vibration attenuation of composite moving beams using active vibration control techniques. A finite element model is developed to reduce the excess vibrations caused by the axial oscillation of the beam. The formulation is based on variational principles. Lagrange multipliers are used to apply the displacement constraints.
Hanif and Sivaneri (2014) and Sivaneri and Hanif (2014) have studied the effect of hygrothermal conditions and failure analysis, respectively on fiber reinforced composite laminates with moving loads. The formulation is carried out for both CLPT and FSDT. The failure analysis uses the maximum-normal-stress criterion. Different fiber volume fraction with varying fiber orientation of the laminate plies are modeled and studied.

1.5 Objectives

The objectives of this research are:

- To analyze the large-deflection of a composite beam using a higher-order shear deformation theory. The formulation of this beam is carried out using the principle of virtual work.
- To determine the nonlinear part of the structural stiffness matrix of a beam made of a composite material.
- To determine the tangential stiffness matrix corresponding to the Newton-Raphson iterative technique.
- To develop a MATLAB code to solve the nonlinear finite element equations for the large-deflection of composite beam using an iterative process.
- To calculate deflection of the composite beam as a function of position under a uniformly distributed load.

1.6 Organization of thesis

Chapter two deals with the beam lay-up configuration, introduction to different plate theories and their displacement distributions, and the formulation of the governing equations using principle of virtual work.

Chapter three details the finite element formulation of the linear and nonlinear stiffness matrices, Gaussian integration procedure, and Newton-Raphson iterative method.

Chapter four presents the results in the form deflections as a function of position for composite beams formulated using cylindrical bending and HSDT, respectively. Conclusions of the present work and recommendations for future work are also included.
2 THEORETICAL FORMULATION

2.1 Introduction

Composite materials have special/significant properties such as high strength to weight ratio and resistance to wear and corrosion. These advantages drive the usage of composite materials over conventional materials. Composite beams are widely used as structural members. These are subjected to axial, transverse and the formulation of large-deflection analysis of a composite beam is described in this chapter along with a systematic reduction of the composite plate theory to a beam.

2.2 Lay-up configuration

There are symmetric and unsymmetric lay-ups. A symmetric laminate is one that has the same number of layers with the same orientation and thickness located symmetrically about the mid-plane; otherwise it is unsymmetric. Figure 2.1 shows the sequence of a lamina stacking and the naming convention of a composite laminate. The total height of the laminate is \( h \), which has \( n \) layers. The mid-plane is located halfway through the thickness of the plate. \( K \) is the lamina number counting from the bottom up and \( z_k \) is the coordinate of the top surface of the \( k^{th} \) lamina.
2.3 Force and Moments Resultants

Figure 2.3 shows the mid-plane of the plate on which positive force and moment resultants acting are represented. $N_x, N_y$ and $N_{xy}$ are the in-plane force resultants acting along $x$ and $y$ directions. $M_x, M_y$ and $M_{xy}$ are the moment resultants.
2.4 Plate theories

Plate theories describe the kinematic behavior of plate elements. Composite laminates are generally treated as plate elements due to the fact that they have larger planar dimensions when compared to the thickness. The most commonly used plate theories are the Classical Laminate Plate Theory (CLPT), First-order Shear Deformation Theory (FSDT), and the Higher-order Shear Deformation Theory (HSDT). The HSDT is employed in this research. The Classical laminate plate theory for composite laminates is an extension of the classical plate theory of isotropic materials. Kirchoff’s hypotheses are used in the derivation of the plate stiffness and compliance equations. The assumptions, as stated by Reddy (1997), for CLPT are:

1. Straight lines perpendicular to the mid-surface (transverse normals) before deformation remain straight after deformation.
2. The transverse normals do not experience elongation. ($\varepsilon_{zz} = 0$)
3. The transverse normals rotate such that they remain perpendicular to the mid-surface after deformation. ($\varepsilon_{xz} = 0$ and $\varepsilon_{yz} = 0$)

In addition to Kirchoff’s hypothesis, the following assumptions are also used:

4. The layers are perfectly bonded together.
5. The material of each layer is linearly elastic and has two planes of material symmetry (i.e., orthotropic).
6. Each layer is of uniform thickness.
7. The strains and displacements are small.
8. The transverse shear stresses on the top and bottom surfaces of the laminate are zero.

From Nagappan (2004), Composites have very low transverse shear modulus compared to their on-axis modulus. In the case of CLPT, the effects of transverse shear are neglected since transverse shear strains ($\gamma_{xz}$ and $\gamma_{yz}$) are assumed to be zero. This may make the CLPT inadequate for the dynamic response even for a beam with a high slenderness ratio. To consider the effect of transverse shear, an FSDT can be used. The FSDT uses the same assumptions as in CLPT except for the third Kirchoff’s hypothesis. In FSDT the transverse normal is assumed to be straight but not perpendicular to the mid-surface after deformation and therefore transverse shear strains are not zero. First order shear deformation theory uses a shear correction factor [Cowper (1996), Vlachoutsis (1992)] to correct the shear strain energy but the zero transverse shear conditions at the top and bottom surfaces are not satisfied. To avoid the shear correction factor and to present the kinematics better than FSDT, higher-order shear deformation theories can be used [Lo, Christensen and Wu (1977); Levinson (1981); Reddy (1984)]. The third order theory is also based on the same assumptions as that of
FSDT, except that the assumption on the straightness of the transverse normal after deformation is relaxed. The transverse normal is no longer inextensible, making the deformations as a function of the thickness coordinate \( z \).

![Deformation of transverse normal for CLPT, FSDT and HSDT](Fig2.4)

In HSDT, the displacement field \( (u, v, w) \) in the \((x, y, z)\) directions, respectively, can be expressed as [Reddy 1997]:

\[
\begin{align*}
    u(x, y, z, t) &= u_0(x, y, t) + z\phi_x(x, y, t) - c_1z^3 \left( \phi_x + c_0 \frac{\partial w}{\partial x} \right) \\
    v(x, y, z, t) &= v_0(x, y, t) + z\phi_y(x, y, t) - c_1z^3 \left( \phi_y + c_0 \frac{\partial w}{\partial y} \right) \\
    w(x, y, z, t) &= w(x, y, t) = w_b(x, y, t) + w_s(x, y, t)
\end{align*}
\]  

(2.1)

where \( u_0 \) and \( v_0 \) are the in-plane displacements at the mid-plane and \( \phi_x \) and \( \phi_y \) are the rotations of a transverse normal about the \( y \) and \( x \) axes respectively. The bending deformation \( w \) consists of a pure bending component \( w_b \) and a shear component \( w_s \). In Eq. (2.1) \( c_0 \) is assumed to be unity while \( c_1 = 0 \) for FSDT and \( c_1 = \frac{4}{3h^2} \) for HSDT.

### 2.5 Principle of Virtual Work

The word virtual means imaginary. A virtual displacement is arbitrary but small, conforms to the kinematic constraints and does not alter the applied loads. Virtual work is done by real load on
a virtual displacement. The principle of Virtual work states that for a system in static equilibrium, the total virtual work done is zero. Mathematically, the principle of virtual work is

\[ \delta W \equiv 0 \]

\[ \Rightarrow \delta W_e + \delta W_i = 0 \]  

(2.2)

where, \( \delta W_e \) is the external virtual work and \( \delta W_i \) is the internal virtual work.

Let \( Q \) be a generalized force on a system resulting in a corresponding generalized displacement \( q \).

External work is defined mathematically as follows

\[ W_e = \int_{0}^{q} Q \, dq \]  

(2.3)

Thus, the external virtual work is

\[ \delta W_e = Q \delta q \]  

(2.4)

Internal Virtual Work can be obtained from virtual strain energy as follows

\[ \delta U = \iiint_{V} \delta U_0 \, dV \]  

(2.5)

where \( U_0 \) is the stain energy density.

\[ \delta W_i = -\delta U \]  

(2.6)

Thus, substituting Eq. 2.6 and Eq. 2.4(\( \delta W_i \) and \( \delta W_e \)) in Principle of Virtual Work Eq. 2.2, we get

\[ \delta W_e = -\delta U \]  

(2.7)

Generally, external work is represented with symbol ‘\( W \)”

Thus, Principle of Virtual Work is

\[ \delta U = \delta W \]  

(2.8)
2.5.1 Kinematic Equations of composite plate

The nonlinear kinematic equations for moderate rotations are given by [Reddy (1997)],

\[\varepsilon_x = \frac{\partial u}{\partial x} + \frac{1}{2} \left( \frac{\partial w}{\partial x} \right)^2\]

\[\varepsilon_y = \frac{\partial v}{\partial y} + \frac{1}{2} \left( \frac{\partial w}{\partial y} \right)^2\]

\[\gamma_{xy} = \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} + \frac{\partial w}{\partial x} \frac{\partial w}{\partial y} \right)\]

(2.9)

\[\gamma_{yz} = \left( \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right)\]

\[\gamma_{xz} = \left( \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} \right)\]

Substituting Eq. (2.9) into Eq. (2.1) we get,

\[\varepsilon_x = \frac{\partial u_0}{\partial x} + \frac{1}{2} \left( \frac{\partial w}{\partial x} \right)^2 + z \frac{\partial \phi_x}{\partial x} - c_1 z^3 \left( \frac{\partial \phi_x}{\partial x} + \frac{\partial^2 w}{\partial x^2} \right)\]

\[\varepsilon_y = \frac{\partial v_0}{\partial y} + \frac{1}{2} \left( \frac{\partial w}{\partial y} \right)^2 + z \frac{\partial \phi_y}{\partial y} - c_1 z^3 \left( \frac{\partial \phi_y}{\partial y} + \frac{\partial^2 w}{\partial y^2} \right)\]

\[\gamma_{xy} = \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} + \frac{\partial w}{\partial x} \frac{\partial w}{\partial y} + z \left( \frac{\partial \phi_x}{\partial y} + \frac{\partial \phi_y}{\partial x} \right) - c_1 z^3 \left( \frac{\partial \phi_x}{\partial y} + \frac{\partial \phi_y}{\partial x} + 2 \frac{\partial^2 w}{\partial x \partial y} \right)\]

(2.10)

\[\gamma_{yz} = \phi_y + \frac{\partial w}{\partial y} - 3c_1 z^2 \left( \phi_y + \frac{\partial w}{\partial y} \right)\]

\[\gamma_{xz} = \phi_x + \frac{\partial w}{\partial x} - 3c_1 z^2 \left( \phi_x + \frac{\partial w}{\partial x} \right)\]

The transverse normal rotations at the mid-plane, \(\phi_x\) and \(\phi_y\) can be written as,

\[\phi_x = \frac{\partial u_0}{\partial z} = - \frac{\partial w_b}{\partial x}\]

\[\phi_y = \frac{\partial v_0}{\partial z} = - \frac{\partial w_b}{\partial y}\]

(2.11)

Then \(\phi_x + \frac{\partial w}{\partial x} = - \frac{\partial w_b}{\partial x} + \frac{\partial w_b}{\partial x} + \frac{\partial w_s}{\partial x} = \frac{\partial w_s}{\partial x}\)
Similarly, \( \phi_y + \frac{\partial w}{\partial y} = \frac{\partial w_s}{\partial y} \) \hspace{1cm} (2.12)

The strains in Eq. (2.10) can also be written as,

\[
\begin{align*}
\varepsilon_x &= \varepsilon_x^{(0)} + z\varepsilon_x^{(1)} + z^3 \varepsilon_x^{(3)} \\
\varepsilon_y &= \varepsilon_y^{(0)} + z\varepsilon_y^{(1)} + z^3 \varepsilon_y^{(3)} \\
\gamma_{xy} &= \gamma_{xy}^{(0)} + z\gamma_{xy}^{(1)} + z^3 \gamma_{xy}^{(3)} \\
\gamma_{yz} &= \gamma_{yz}^{(0)} + z^2 \gamma_{yz}^{(2)} \\
\gamma_{xz} &= \gamma_{xz}^{(0)} + z^2 \gamma_{xz}^{(2)}
\end{align*}
\] \hspace{1cm} (2.13)

Where,

\[
\begin{align*}
\varepsilon_x^{(0)} &= \frac{\partial u_0}{\partial x} + \frac{1}{2} \left( \frac{\partial w_b}{\partial x} \right)^2 + \frac{1}{2} \left( \frac{\partial w_s}{\partial x} \right)^2 \\
\varepsilon_x^{(1)} &= - \frac{\partial^2 w_b}{\partial x^2} \\
\varepsilon_x^{(3)} &= - c_1 \frac{\partial^2 w_s}{\partial x^2} \\
\varepsilon_y^{(0)} &= \frac{\partial v_0}{\partial y} + \frac{1}{2} \left( \frac{\partial w_b}{\partial y} \right)^2 + \frac{1}{2} \left( \frac{\partial w_s}{\partial y} \right)^2 \\
\varepsilon_y^{(1)} &= - \frac{\partial^2 w_b}{\partial y^2} \\
\varepsilon_y^{(3)} &= - c_1 \frac{\partial^2 w_s}{\partial y^2} \\
\gamma_{xy}^{(0)} &= \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} + \left( \frac{\partial w_b}{\partial x} + \frac{\partial w_s}{\partial x} \right) \left( \frac{\partial w_b}{\partial y} + \frac{\partial w_s}{\partial y} \right) \\
\gamma_{xy}^{(1)} &= - 2 \frac{\partial^2 w_b}{\partial x \partial y} \\
\gamma_{xy}^{(3)} &= - 2 c_1 \frac{\partial^2 w_s}{\partial x \partial y}
\end{align*}
\]

The term \( \left( \frac{\partial w_b}{\partial x} + \frac{\partial w_s}{\partial x} \right) \left( \frac{\partial w_b}{\partial y} + \frac{\partial w_s}{\partial y} \right) \) is the above expression is a nonlinear term.
\[ \gamma_{yz}^{(0)} = \frac{\partial w_s}{\partial y} \]
\[ \gamma_{yz}^{(2)} = -3c_1 \frac{\partial w_s}{\partial y} \]
\[ \gamma_{yz}^{(0)} = \frac{\partial w_s}{\partial y} \]
\[ \gamma_{xz}^{(2)} = -3c_1 \frac{\partial w_s}{\partial x} \]

(2.14)

### 2.5.2 Virtual Strain Energy for a Plate

The total virtual strain energy for a plate is given as,

\[ \delta U = \iiint_V \left[ \sigma_x \delta \varepsilon_x + \sigma_y \delta \varepsilon_y + \tau_{xy} \delta \gamma_{xy} + \tau_{yz} \delta \gamma_{yz} + \tau_{xz} \delta \gamma_{xz} \right] dV \]  

(2.14)

where, \( \delta \varepsilon_x, \delta \varepsilon_y, \delta \gamma_{xy}, \delta \gamma_{yz}, \) and \( \delta \gamma_{xz} \) are the virtual strains and \( V \) is the volume of the plate. Separating the volume integral into an integral over the thickness coordinate \( Z \) and an area integral in the \( x, y \) directions we get,

\[ \delta U = \iint_A \int_{-h/2}^{h/2} \left[ \sigma_x \delta \varepsilon_x + \sigma_y \delta \varepsilon_y + \tau_{xy} \delta \gamma_{xy} + \tau_{yz} \delta \gamma_{yz} + \tau_{xz} \delta \gamma_{xz} \right] dAdz \]  

(2.15)

Defining Stress resultants as follows

\( (N_x, N_y, N_{xy}) = \int_{-h/2}^{-h/2} (\sigma_x, \sigma_y, \tau_{xy}) dz \)

\( (M_x, M_y, M_{xy}) = \int_{-h/2}^{-h/2} (\sigma_x, \sigma_y, \tau_{xy}) zdz \)

\( (P_x, P_y, P_{xy}) = \int_{-h/2}^{-h/2} (\sigma_x, \sigma_y, \tau_{xy}) z^2 dz \)

\( (Q_x, Q_y) = \int_{-h/2}^{-h/2} (\tau_{xy}, \tau_{yz}) dz \)

\( (R_x, R_y) = \int_{-h/2}^{-h/2} (\tau_{xy}, \tau_{yz}) z^2 dz \)  

(2.16)
The quantities \(N, N_y, N_{xy}\) are the in-plane force resultants, \(M, M_y, M_{xy}\) are the moment resultants, \(Q, Q_y\) are the transverse force resultants and \(P, P_y, P_{xy}, R, R_y\) are the higher order stress resultants. Then the strain energy equation of the plate simplifies to:

\[
\delta U = \int_A \left[ N_x \delta \varepsilon_x^{(0)} + M_x \delta \varepsilon_x^{(1)} + P_x \delta \varepsilon_x^{(3)} + N_y \delta \varepsilon_y^{(0)} + M_y \delta \varepsilon_y^{(1)} + P_y \delta \varepsilon_y^{(3)} + N_{xy} \delta \gamma_{xy}^{(0)} + M_{xy} \delta \gamma_{xy}^{(1)} + P_{xy} \delta \gamma_{xy}^{(3)} + Q_x \delta \gamma_{x}^{(0)} + R_x \delta \gamma_{zx}^{(2)} + Q_y \delta \gamma_{yz}^{(0)} + R_y \delta \gamma_{yz}^{(2)} \right] dA
\]  

(2.17)

### 2.5.3 Constitutive Equations

The relation between the stress resultants and strains are given by:

\[
\begin{align*}
\{N\} &= [A] \{\varepsilon^{(0)}\} \\
\{M\} &= [B] \{\varepsilon^{(1)}\} \\
\{P\} &= [E] \{\varepsilon^{(3)}\} \\
\end{align*}
\]

(2.18)

\[
\begin{align*}
\{Q\} &= [A] \{\gamma^{(0)}\} \\
\{R\} &= [D] \{\gamma^{(2)}\} \\
\end{align*}
\]

(2.19)

Vectors \(\{N\}\) and \(\{M\}\) represent the force and moment resultants. Vector \(\{Q\}\) denote the transverse force resultants, while vectors \(\{P\}\) and \(\{R\}\) represent the higher-order stress resultants. Matrices \([A]\), \([B]\) and \([D]\) contain the extension stiffness, bending-extension coupling and bending stiffness coefficients while matrices \([E]\), \([F]\) and \([H]\) have higher-order stiffness coefficient terms. The coefficient matrices in Eq. (2.18) are obtained from,

\[
(A_{ij}, B_{ij}, D_{ij}, E_{ij}, F_{ij}, H_{ij}) = \sum_{k=1}^{n} \int_{z_{k-1}}^{z_k} \tilde{Q}_{ij}^{(k)}(1, z, z^2, z^3, z^4, z^6) dz
\]

(2.20)

The square matrices in Eq. (2.18) are of order 3 x 3 and the stiffness coefficients are defined for \(i, j = 1, 2, 6\). The \(\tilde{Q}_{ij}^{(k)}\) denotes the off-axis material stiffness coefficients of the \(k^{th}\) layer. Matrices in Eq. (2.19) are obtained from,

\[
(A_{ij}, D_{ij}, F_{ij}) = \sum_{k=1}^{n} \int_{z_{k-1}}^{z_k} \tilde{Q}_{ij}^{(k)}(1, z^2, z^6) dz
\]

(2.21)

where, \([A]\), \([D]\) and \([F]\) are 2 x 2 matrices with \(i, j = 4, 5\).

### 2.5.4 Reduction of Plate Equations to Beams [Nagappan (2004)]

For isotropic materials beam theories were developed first since they are much simpler than the corresponding plate theories whereas plate theories were developed first in case of
composite materials. Chandrasekaran and Sivaneri (2000) studied an efficient way to reduce these plate theories to corresponding beam theories. This process for HSDT is outlined in this section.

For beams, the lateral resultants forces are negligible. Hence, $N_y, M_y, P_y$ are set to zero in Eq. (2.18). Similarly, $Q_y$ and $R_y$ are set to zero in Eq. (2.19). By rearranging Eq. (2.18) we get,

$$
\begin{bmatrix}
N_x \\
N_{xy}
\end{bmatrix} =
\begin{bmatrix}
A_{11} & A_{16} & B_{11} & B_{16} & E_{11} & E_{16} & A_{12} & B_{12} & E_{12} \\
A_{16} & A_{66} & B_{16} & B_{66} & E_{16} & E_{66} & A_{26} & B_{26} & E_{26}
\end{bmatrix}
\begin{bmatrix}
\xi_x^{(0)} \\
\eta_x^{(0)} \\
\xi_x^{(1)} \\
\eta_x^{(1)} \\
\xi_x^{(3)} \\
\eta_x^{(3)} \\
\xi_y^{(3)} \\
\eta_y^{(3)}
\end{bmatrix}
$$  

It can be observed that

$$[T^{21}] = [T^{12}]^T$$  

Expanding Eq. (2.23)

$$\{\bar{N}\} = [T^{11}]\{\bar{\xi}\} + [T^{12}]\{\bar{\eta}\}$$  

Omitting $\{\bar{\eta}\}$ in Eq. (2.25) we get,

$$\{\bar{N}\} = [T]\{\bar{\xi}\}$$  

where $[T] = ([T^{11}] - [T^{12}][T^{22}]^{-1}[T^{21}])$

Similarly, Eq. (2.19) can be rearranged and partitioned by setting $Q_y = R_y = 0,$
\[ \begin{pmatrix} Q_x \\ R_x \\ \vdots \\ 0 \\ 0 \end{pmatrix} = \begin{bmatrix} A_{55} & D_{55} & A_{45} & D_{45} \\ D_{55} & F_{55} & D_{45} & F_{45} \\ \vdots & \vdots & \vdots & \vdots \\ A_{45} & D_{45} & A_{44} & D_{44} \\ D_{45} & F_{45} & D_{44} & F_{44} \end{bmatrix} \begin{pmatrix} y_{xz}^{(0)} \\ y_{xz}^{(2)} \\ y_{yz}^{(2)} \\ y_{yz}^{(0)} \end{pmatrix} \] (2.28)

Say the notations, \( w_s' = \frac{\partial w_s}{\partial x} \) and \( w_s^y = \frac{\partial w_s}{\partial y} \) in Eq. (2.13), the strain vector in Eq. (2.28) becomes,

\[ \begin{bmatrix} y_{xz}^{(0)}, y_{xz}^{(2)}, y_{yz}^{(2)}, y_{yz}^{(0)} \end{bmatrix} = \begin{bmatrix} w_s' - 3c_1w_s^y \\ w_s' \end{bmatrix} \] (2.29)

Define

\[ D_{ij}^* = A_{ij} - 6c_1D_{ij} + 9c_1^2F_{ij} \]
\[ Q_x^* = Q_x - 3c_1R_x \]
\[ Q_y^* = Q_y - 3c_1R_y \] (2.30)

Substituting Eq. (2.30) into Eq. (2.28) we get,

\[ \begin{bmatrix} Q_y^* \\ Q_x^* \end{bmatrix} = K \begin{bmatrix} D_{44}^* & D_{45}^* \\ D_{45}^* & D_{55}^* \end{bmatrix} \begin{bmatrix} \{w_s^y\} \\ \{w_s'\} \end{bmatrix} \] (2.31)

A factor \( K \) known as shear correction factor in the Eq. (2.31) is introduced even though HSDT does not require. This is done to obtain FSDT results from the HSDT formulation by setting \( c_1 = 0 \) and \( K = 5/6 \). For HSDT case \( K \) will be one.

For a beam, \( Q_y^* \) is set to 0. Thus, solving Eq. (2.31) we get,

\[ Q_x^* = KD_{55}^{**}w_s' \] (2.32)

Where \( D_{55}^{**} = D_{55}^* - \frac{D_{45}^{*2}}{D_{44}^*} \) (2.33)

**2.5.5 Virtual Strain Energy of a Composite Beam**

To obtain strain energy for beam, employ the systematic way discussed above i.e \( N_y = M_y = P_y = Q_y = R_y = 0 \). For a rectangular beam of width \( b \) and length \( L \), the area integral in Eq. (2.17) is changed to a line integral along \( x \) and further substituting kinematic Eqs. (2.13) and (2.14) in Eq. (2.17) and following notations are used
\( (\cdot)' = \frac{\partial (\cdot)}{\partial x} \)

\( (\cdot)' = \frac{\partial (\cdot)}{\partial y} \)

\( (\cdot)'' = \frac{\partial^2 (\cdot)}{\partial x^2} \)

\( (\cdot)'y = \frac{\partial^2 (\cdot)}{\partial x \partial y} \)

\[
y_0 = \frac{\partial u_0}{\partial y} + \frac{\partial v_0}{\partial x} \tag{2.34}
\]

Then \( \delta U \) becomes,

\[
\delta U = b \int_0^l \left[ N_x (\delta u'_0 + w'_b \delta w'_b + w'_s \delta w'_s) - M_x \delta w''_b - P_x c_1 \delta w''_s + N_{xy} (\delta y_0 + (\delta w'_b + \delta w'_s)(w^y_b + w^y_s) + (w'_b + w'_s)(\delta w^y_b + \delta w^y_s)) \right. - \left. 2M_{xy} \delta w^y_b - 2P_{xy} c_1 \delta w^y_s + Q_x \delta w_s \right] dx \tag{2.35}
\]

Where,

\[
N_x (\delta u'_0 + w'_b \delta w'_b + w'_s \delta w'_s) = N_x \delta u'_0 + N_x w'_b \delta w'_b + N_x w'_s \delta w'_s \tag{2.36}
\]

From constitutive equation Eq. (2.22), substituting \( N_x, M_x, P_x, N_{xy}, M_{xy} \) and \( P_{xy} \) in the above Eq. (2.36) gives,

\[
N_x (\delta u'_0 + w'_b \delta w'_b + w'_s \delta w'_s) = (T_{11} u'_0 + T_{12} y_0 - T_{13} w''_b - 2T_{14} w'^y_b - c_1 T_{15} w''_s - 2 c_1 T_{16} w'^y_s) \delta u'_0 + N_x w'_b \delta w'_b + N_x w'_s \delta w'_s + \left( \frac{T_{11}}{2} w'_b \delta u'_0 w'_b + \frac{T_{11}}{2} w'_s \delta u'_0 w'_s \right) + T_{12} (w'_b w^y_b \delta u'_0 + w'_s w^y_s \delta u'_0 + w'_b w^y_b \delta u'_0 + w'_s w^y_s \delta u'_0) \right)
\]

\[
-M_x \delta w''_b = -\left( T_{31} u'_0 + T_{32} y_0 - T_{33} w''_b - 2T_{34} w'^y_b - c_1 T_{35} w''_s - 2 c_1 T_{36} w'^y_s \right) \delta w''_b + \left( \frac{T_{31}}{2} w'_b \delta w''_b w'_b + \frac{T_{31}}{2} w'_s \delta w''_b w'_s \right) + T_{32} (w'_b w^y_b \delta w''_b + w'_s w^y_s \delta w''_b + w'_b w^y_b \delta w''_b + w'_s w^y_s \delta w''_b) \right)
\]
\[-P_x c_1 \delta w_s'' = -c_1 (T_{51} u_0 + T_{52} \gamma_0 - T_{53} w_b'' - 2T_{54} w_b''') - c_1 T_{55} w'_s - 2c_1 T_{56} w_s'') \delta w'_s \]
\[= \frac{T_{51}}{2} w'_b \delta w''_s + \frac{T_{51}}{2} w'_s \delta w'''_s \]
\[+ T_{55} (w'_b w''_b \delta w''_s + w'_b w''_s \delta w'''_s + w'_s w''_b \delta w'''_s + w'_s w''_s \delta w''''_s) \]
\[+ N_{xy} \left( \left( \delta w_b + \delta w_s' \right) \left( w'_b + w''_b \right) + \left( w'_s + w''_s \right) \left( \delta w_b' + \delta w_s'' \right) \right) \]
\[= N_{xy} \delta \gamma_0 + N_{xy} \left( \left( w'_b + w''_b \right) \delta w'_b + \left( w'_s + w''_s \right) \delta w''_s \right) \]
\[+ N_{xy} \left( \left( w'_b + w''_b \right) \delta w'_s + \left( w'_s + w''_s \right) \delta w'''_s \right) \]
\[= \left( T_{41} u_0 + T_{42} \gamma_0 - T_{43} w_b'' - 2T_{44} w_b''' - c_1 T_{45} w'_s - 2c_1 T_{46} w''_s \right) \delta w''_s \]
\[+ \frac{T_{41}}{2} w'_b \delta \gamma_0 w_b' + \frac{T_{41}}{2} w'_s \delta \gamma_0 w'_s \]
\[+ T_{42} \left( w'_b w''_b \delta w''_b + w'_b w''_b \delta w'''_b + w'_s w''_b \delta w''''_b + w'_s w''_s \delta w''''_s \right) \]
\[-2M_{xy} \delta w_b'' = -2 \left( T_{61} u_0 + T_{62} \gamma_0 - T_{63} w_b'' - 2T_{64} w_b''' - c_1 T_{65} w'_s - 2c_1 T_{66} w''_s \right) \delta w_b'' \]
\[= -2 \left( \frac{T_{61}}{2} w'_b \delta w''_b w'_b + \frac{T_{61}}{2} w'_s \delta w'''_b w'_s \right) \]
\[+ T_{62} \left( w'_b w''_b \delta w''_b + w'_b w''_b \delta w'''_b + w'_s w''_b \delta w''''_b + w'_s w''_s \delta w''''_s \right) \]
\[-2P_{xy} c_1 \delta w_s''' = -2c_1 \left( T_{61} u_0 + T_{62} \gamma_0 - T_{63} w_b'' - 2T_{64} w_b''' - c_1 T_{65} w'_s - 2c_1 T_{66} w''_s \right) \delta w''_s \]
\[= -2c_1 \left( \frac{T_{61}}{2} w'_b \delta w''_s w'_b + \frac{T_{61}}{2} w'_s \delta w'''_s w'_s + T_{62} \left( w'_b w''_b \delta w''_s + w'_b w''_b \delta w'''_s + w'_s w''_b \delta w''''_s \right) \right) \]

### 2.5.6 Large Deflection Cylindrical Bending of Composite Plates

Consider a laminated plate as shown in figure 2.5. Suppose the plate is long in the x – direction and has finite dimensions along the y – direction and subjected to transverse load $P_z(x, y)$ which is uniform at any section parallel to the y axis. In such a case plate bends into a cylindrical surface and is similar to beam bending.

The kinematic equations are as follows
\[
\epsilon_x = u' + \frac{1}{2}(w')^2 - zw''
\]
\[
\epsilon_y = 0
\]
\[
\gamma_{xy} = 0
\]

(2.38)

The constitutive equations are

\[
\begin{bmatrix}
\sigma_x \\
\sigma_y \\
\sigma_z
\end{bmatrix}_K = [\overline{Q}]_K \begin{bmatrix}
\epsilon_x \\
\epsilon_y \\
\epsilon_z
\end{bmatrix}
\]

(2.39)

Substituting Eq. (2.38) in the above gives

\[
(\sigma_x)_K = (\overline{Q}_{11})_K \epsilon_x = (\overline{Q}_{11})_K \left[u' + \frac{1}{2}(w')^2 - zw''\right]
\]

(2.40)

### 2.5.7 Virtual Strain Energy for Cylindrical Bending

The total virtual strain energy for cylindrical bending is given as,

\[
\delta U = \iiint_V \left[\sigma_x \delta \epsilon_x\right] dV
\]

(2.41)

where \(\delta \epsilon_x\) is the virtual strains and \(V\) is the volume of the plate. The rectangular beam has width \(b\) in y direction, length \(L\) in x axis and thickness \(h\) in z direction. Rewriting volume integral in terms of area and thickness integrals we get,

\[
\delta U = b \int_0^L \int_{-h/2}^{h/2} \sigma_x \delta \epsilon_x dx dz
\]

(2.42)
Now the $\delta U$ can be written in terms of the deformation quantities as

$$\delta U = b \int_0^L \left\{ \left[ A_{11} \left( u' + \frac{1}{2} (w')^2 \right) - B_{11} w'' \right] (\delta u' + w' \delta w') \left[ -B_{11} \left( u' + \frac{1}{2} (w')^2 \right) + \right. \right. \left. \left. D_{11} w^{11} \right] \delta w'' \right\} dx \quad (2.43)$$
3 FINITE ELEMENT METHOD

3.1 Introduction

The finite element method can be employed to solve partial differential equations where the domain is first discretized into small elements called finite elements. Figure 3.1 shows the classification of methods to solve partial differential equations. With the increase in number of elements or nodes or both, the finite element solution approaches analytical solution. Based on this $h$ version, $p$ version and $h$-$p$ version finite element formulations are available. In the $h$-version, accuracy generally increases with the increase in number of elements, in the $p$-version number of internal nodes is increased to improve the accuracy and in the $h$-$p$ version both elements and nodes are increased to attain accuracy. In the present research, the $h$-$p$ version is used.

![Classification of methods to solve partial differential equations](image)

3.2 Finite element shape functions

Sreeram and Sivaneri (1997) conducted a convergence study on an isotropic beam problem and concluded that four elements with three internal nodes each produce an accurate solution. In the present research, the composite beam is divided into four elements, each having three internal nodes and two end nodes. The $C^0$ continuity is satisfied by certain variables and their shape functions are derived using Lagrangian interpolating polynomials while Hermitian polynomials are used in deriving other shape functions which obey $C^1$ continuity. For the
variables that employ $C^1$ continuity, only the end nodes have slope degrees of freedom as the slope continuity at the internal nodes is automatically satisfied.

Figure 3.2 shows finite element beam representation. The beam considered is divided into four elements. Each element has three internal nodes and two end nodes. The length of the element is $l_e$, $\xi$ is the natural coordinate and $x_e$ is the independent variable measured from left end of the beam. The dependent variables are:

$u$ = axial deformation at mid-plane

$\gamma$ = mid-plane shear strain

$w_b$ = transverse bending deformation

$w_s$ = transverse shear deformation
\( w_b^y \) = twist angle associated with the bending deformation

\( w_s^y \) = twist angle associated with the shear deformation

The variables \( u, \gamma, w_b^y, w_s^y \) obey \( C^0 \) continuity while \( w_b \) and \( w_s \) have slope degrees of freedom at the end nodes and thus \( C^1 \) continuity is assured.

For each element, an intrinsic coordinate \( \xi \) ranging from -1 to 1 is described with its origin at the center as shown in Fig. 3.2. The elemental coordinates can be transformed to the intrinsic coordinates with the following relation

\[
x_e = \frac{l_e}{2} (\xi + 1) \\
dx_e = \frac{l_e}{2} d\xi
\]

(3.1)

where \( l_e \) being element length. The shape functions for the variables that follow \( C^0 \) continuity and \( C^1 \) continuity are derived respectively. The axial displacement (\( u \)) and lateral displacement component due to bending (\( w_b \)) are represented as

\[
u(\xi) = \sum_{i=0}^{4} a_i \xi^i
\]

\[
w(\xi) = \sum_{j=0}^{6} b_j \xi^j
\]

(3.2)

The above equations can be written in matrix form as follows

\[
u(\xi) = [\xi^i] [a_i]
\]

\[
w(\xi) = [\xi^j] [b_j]
\]

(3.3)

Where the \( a_i \) are determined by the following conditions

\[
u(-1) = u_1
\]

\[
u(-0.5) = u_2
\]

\[
u(0) = u_3
\]

\[
u(0.5) = u_4
\]

\[
u(1) = u_5
\]

(3.4)
By solving the above equations and substituting in Eq. (3.3) we get,

\[ u(\xi) = [H_{L1}(\xi) \ldots H_{L5}(\xi)] \begin{bmatrix} u_1 \\ \vdots \\ u_5 \end{bmatrix} \]

where \( H_{L1}(\xi), H_{L2}(\xi), \ldots, H_{L5}(\xi) \) are called as Lagrange shape functions. They are

\[
H_{L1} = \frac{1}{6} \xi - \frac{1}{6} \xi^2 - \frac{2}{3} \xi^3 + \frac{2}{3} \xi^4
\]

\[
H_{L2} = -\frac{4}{3} \xi + \frac{8}{3} \xi^2 + \frac{4}{3} \xi^3 + \frac{8}{3} \xi^4
\]

\[
H_{L3} = 1 - 5\xi^2 + 4\xi^4
\]

\[
H_{L4} = \frac{4}{3} \xi + \frac{8}{3} \xi^2 - \frac{4}{3} \xi^3 - \frac{8}{3} \xi^4
\]

\[
H_{L5} = \frac{1}{6} \xi - \frac{1}{6} \xi^2 - \frac{2}{3} \xi^3 + \frac{2}{3} \xi^4
\]

And \( b_j \) can be determined by the following conditions

\[
w_b(-1) = w_{b_1}
\]

\[
\frac{l_e}{2} \frac{d}{d\xi} w_b(-1) = w_{b_1}'
\]

\[
w_b(-0.5) = w_{b_2}
\]

\[
w_b(0) = w_{b_3}
\]

\[
w_b(0.5) = w_{b_4}
\]

\[
w_b(1) = w_{b_5}
\]

\[
\frac{l_e}{2} \frac{d}{d\xi} w_b(1) = w_{b_5}'
\]

Solving the above equations for \( b_j \) we get,
where \( H_1(\xi), H_2(\xi), \ldots, H_7(\xi) \) are called as Hermite shape functions. They are

\[
H_1 = \frac{1}{9} \left( \frac{17}{4} \xi - 5\xi^2 - \frac{79}{4} \xi^3 + \frac{47}{2} \xi^4 + 11\xi^5 - 14\xi^6 \right)
\]

\[
H_2 = \frac{l_e}{6} \left( \frac{1}{4} \xi - \frac{1}{4} \xi^2 - \frac{5}{4} \xi^3 + \frac{5}{4} \xi^4 + \xi^5 - \xi^6 \right)
\]

\[
H_3 = \frac{16}{9} \left( -\xi + 2\xi^2 + 2\xi^3 - 4\xi^4 - \xi^5 + 2\xi^6 \right)
\]

\[
H_4 = 1 - 6\xi^2 + 9\xi^4 - 4\xi^6
\]

\[
H_5 = \frac{16}{9} \left( \xi + 2\xi^2 - 2\xi^3 - 4\xi^4 + \xi^5 + 2\xi^6 \right)
\]

\[
H_6 = \frac{1}{9} \left( -\frac{17}{4} \xi - 5\xi^2 + \frac{79}{4} \xi^3 + \frac{47}{2} \xi^4 - 11\xi^5 - 14\xi^6 \right)
\]

\[
H_7 = \frac{l_e}{6} \left( \frac{1}{4} \xi + \frac{1}{4} \xi^2 - \frac{5}{4} \xi^3 - \frac{5}{4} \xi^4 + \xi^5 + \xi^6 \right)
\]

### 3.3 Element stiffness Matrix formulation

The elemental stiffness matrix is obtained from the virtual strain energy equation reduced for the beam.

\[
\delta U_e = [\delta q_e][K_e][q_e]
\] (3.10)

Where \( U_e \) represents the elemental strain energy, \( \{q_e\} \) denotes the vector of element degrees of freedom and \( [K_e] \) represents the elemental stiffness matrix. The real and virtual displacement fields can be represented in terms of shape functions and the corresponding nodal degrees of freedom.

For example, expressions for mid-plane shear and bending displacements are given as,

\[
\gamma(x) = [H_L][q_y]
\] (3.11)

\[
\delta \gamma(x) = [\delta q_y][H_L]
\]
\[
\begin{align*}
    w_b(x) &= \left[ H \right] \{ q_{wb} \} \\
    \delta w_b(x) &= \left[ \delta q_{wb} \right] \{ H \}
\end{align*}
\]

where \( \{ q_\gamma \} \) and \( \{ q_{wb} \} \) are the vectors of elemental nodal degrees of freedom for the variables \( \gamma \) and \( w_b \) respectively. Using these above expressions and similar ones for other variables in the virtual strain energy expression, Eq. (2.35), and then comparing with Eq. (3.10) we get the stiffness matrix.

The element stiffness matrix has linear and nonlinear parts as the governing equations are nonlinear. Each stiffness matrix is partitioned into 36 submatrices. The linear stiffness matrix is a symmetric matrix while the nonlinear stiffness matrix is not symmetrical.

### 3.3.1 Linear Element Stiffness Matrix for HSDT

The element has a total of 34 degrees of freedom. The stiffness matrix is partitioned into 36 submatrices. The following is the submatrix representation for the linear part of the element stiffness matrix.

\[
[K_{le}] = \begin{bmatrix}
 [K_{uu}] & [K_{uy}] & [K_{uw_b}] & [k_{uw_s}] & [K_{uw_b}^\gamma] & [K_{uw_s}^\gamma] \\
 [K_{uy}] & [K_{yy}] & [K_{yw_b}] & [k_{yw_s}] & [K_{yw_b}^\gamma] & [K_{yw_s}^\gamma] \\
 [K_{uw_b}] & [K_{yw_b}] & [K_{yw_s}] & [k_{yw_b}^\gamma] & [K_{yw_b}^{\gamma y}] & [K_{yw_s}^{\gamma y}] \\
 symm & [K_{uw_s}] & [K_{uw_b}^\gamma] & [k_{uw_b}^{\gamma y}] & [K_{uw_s}^{\gamma y}] & [K_{uw_s}^{\gamma y}] \\
 [K_{uy}] & [K_{uw_s}] & [K_{uw_b}^\gamma] & [k_{uw_b}^{\gamma y}] & [K_{uw_s}^{\gamma y}] & [K_{uw_s}^{\gamma y}] \\
 [K_{uy}] & [K_{uy}] & [K_{uw_b}] & [k_{uw_s}] & [K_{uw_b}^\gamma] & [K_{uw_s}^\gamma] \\
\end{bmatrix}
\]  

(3.14)

Where,

\[
[K_{uu}] = b \int_0^{l_e} T_{11} \{ H_{L'} \} [H_{L'}] \ dx_e
\]

\[
[K_{uy}] = b \int_0^{l_e} T_{12} \{ H_{L'} \} [H_{L}] \ dx_e
\]

\[
[K_{uw_b}] = b \int_0^{l_e} T_{13} \{ H_{L'} \} [H''_{L}] \ dx_e
\]
\[
[K_{uw_s}] = -bc_1 \int_{T_{13}} \{H'_L\} \{H''\} \, dx_e
\]

\[
[K_{uw_b^\gamma}] = -2b \int_{T_{14}} \{H'_L\} \{H'_L\} \, dx_e
\]

\[
[K_{uw_s^\gamma}] = -2bc_1 \int_{T_{16}} \{H'_L\} \{H'_L\} \, dx_e
\]

\[
[K_{\gamma\gamma}] = b \int_{T_{22}} \{H_L\} \{H_L\} \, dx_e
\]

\[
[K_{\gamma w_b}] = -b \int_{T_{23}} \{H_L\} \{H''\} \, dx_e
\]

\[
[K_{\gamma w_s}] = -bc_1 \int_{T_{25}} \{H_L\} \{H''\} \, dx_e
\]

\[
[K_{\gamma w_b^\gamma}] = -2b \int_{T_{24}} \{H_L\} \{H'_L\} \, dx_e
\]

\[
[K_{\gamma w_s^\gamma}] = -2bc_1 \int_{T_{26}} \{H_L\} \{H'_L\} \, dx_e
\]

\[
[K_{w_bw_b}] = b \int_{T_{33}} \{H''\} \{H''\} \, dx_e
\]

\[
[K_{w_bw_s}] = bc_1 \int_{T_{35}} \{H''\} \{H''\} \, dx_e
\]

\[
[K_{w_bw_b^\gamma}] = 2b \int_{T_{34}} \{H''\} \{H'_L\} \, dx_e
\]

\[
[K_{w_bw_s^\gamma}] = 2bc_1 \int_{T_{36}} \{H''\} \{H'_L\} \, dx_e
\]
\[
[K_{w_{ws}}] = b \int_{0}^{l_e} D_{55}^{*} \{H\}' \{H\}' d x_e + b c_1^2 \int_{0}^{l_e} T_{55} \{H''\}' \{H''\}' d x_e
\]

\[
[K_{w_{wb}}^y] = 2 b c_1 \int_{0}^{l_e} T_{54} \{H''\}' \{H_L^1\}' d x_e
\]

\[
[K_{w_{ws}}^y] = 2 b c_1^2 \int_{0}^{l_e} T_{56} \{H''\}' \{H_L^1\}' d x_e
\]

\[
[K_{w_{wb}}^{y, y}] = 4 b \int_{0}^{l_e} T_{44} \{H_L^1\}' \{H_L^1\}' d x_e
\]

\[
[K_{w_{ws}}^{y, y}] = 4 b c_1 \int_{0}^{l_e} T_{46} \{H_L^1\}' \{H_L^1\}' d x_e
\]

\[
[K_{w_{wb}}^{y, y, y}] = 4 b c_1^2 \int_{0}^{l_e} T_{66} \{H_L^1\}' \{H_L^1\}' d x_e
\]  

(3.15)

### 3.3.2 Nonlinear Element Stiffness Matrix for HSDT

The following is the submatrix representation for the nonlinear part of the stiffness matrix.

\[
[K_{NL_e}] =
\begin{bmatrix}
0 & 0 & [K_{uw_b}] & [K_{uw_s}] & [K_{uw_b}^y] & [K_{uw_s}^y] \\
0 & 0 & [K_{yw_b}] & [K_{yw_s}] & [K_{yw_b}^y] & [K_{yw_s}^y] \\
[K_{wb,u}] & [K_{wb,y}] & [K_{wbw_b}] & [K_{wbw_s}] & [K_{wbw_b}^y] & [K_{wbw_s}^y] \\
[K_{ws,u}] & [K_{ws,y}] & [K_{wsbw_b}] & [K_{wsbw_s}] & [K_{wsbw_b}^y] & [K_{wsbw_s}^y] \\
[K_{w^y,u}] & [K_{w^y,b}] & [K_{w^yw_b}] & [K_{w^yw_s}] & [K_{w^yw_b}^y] & [K_{w^yw_s}^y] \\
[K_{w^y,s,u}] & [K_{w^y,s,b}] & [K_{w^yw^y_b}] & [K_{w^yw^y_s}] & [K_{w^yw^y_b}^y] & [K_{w^yw^y_s}^y]
\end{bmatrix}
\]  

(3.16)

Where,

\[
[K_{uw_b}] = b \int_{0}^{l_e} T_{11}^1 \frac{1}{2} w_b^c \{H_L^1\}' \{H\}' d x_e
\]

\[
[K_{uw_s}] = b \int_{0}^{l_e} T_{11}^1 \frac{1}{2} w_s^c \{H_L^1\}' \{H\}' d x_e
\]
\[
\begin{align*}
[K_{u\omega^y}] &= b \int_{0}^{l_e} T_{12} (w'_b + w'_s)[H'_L][H'] \, dx_e = [K_{u\omega^y}] \\
[K_{\gamma w_b}] &= b \int_{0}^{l_e} \frac{T_{21}}{2} w'_b[H_L][H'] \, dx_e \\
[K_{\gamma w_s}] &= b \int_{0}^{l_e} \frac{T_{21}}{2} w'_s[H_L][H'] \, dx_e \\
[K_{\gamma w^y}] &= b \int_{0}^{l_e} T_{22} (w'_b + w'_s)[H_L][H'] \, dx_e = [K_{\gamma w^y}] \\
[K_{\omega \omega^y}] &= b \int_{0}^{l_e} T_{11} w'_b[H_L][H'] \, dx_e + b \int_{0}^{l_e} T_{12} (w'_b + w'_s)[H'][H'_L] \, dx_e \\
[K_{\omega \omega^y}] &= b \int_{0}^{l_e} T_{12} (w'_b + w'_s)[H'][H'_L] \, dx_e + b \int_{0}^{l_e} T_{22} (w'_b + w'_s)[H'][H'_L] \, dx_e \\
[K_{\omega \omega^y}] &= -b \int_{0}^{l_e} \left( \frac{T_{31}}{2} w'_b[H'''][H'] - T_{13} w'_b[H'][H'''] - \frac{T_{11}}{2} (w'_b)^2[H'] \right) \, dx_e \\
&\quad + T_{23} (w'_b + w'_s)[H'][H'''] + \frac{T_{21}}{2} (w'_b + w'_s) w'_b[H'][H'] \right) \, dx_e \\
[K_{\omega \omega^y}] &= -b \int_{0}^{l_e} \left( \frac{T_{31}}{2} w'_b[H'][H'] + c_T w'_b[H'][H'''] - \frac{T_{11}}{2} (w'_b w'_s)[H'][H'] \\
&\quad + c_T T_{23} (w'_b + w'_s)[H'][H'''] + \frac{T_{21}}{2} (w'_b + w'_s) w'_b[H'][H'] \right) \, dx_e \\
[K_{\omega \omega^y}] &= b \int_{0}^{l_e} \left( -T_{32} (w'_b + w'_s)[H'''][H_L] - 2T_{14} w'_b[H'][H'_L] + T_{12} w'_b[H'][H'_L] + T_{24} (w'_b + w'_s)[H'][H'_L] \\
&\quad - 2T_{23} (w'_b + w'_s)[H'][H'_L] + T_{23} (w'_b + w'_s)[H'][H'_L] \right) \, dx_e \\
[K_{\omega \omega^y}] &= b \int_{0}^{l_e} \left( -T_{32} (w'_b + w'_s)[H'''][H_L] - 2T_{16} w'_b[H'][H'_L] + T_{12} w'_b[H'][H'_L] + T_{24} (w'_b + w'_s)[H'][H'_L] \\
&\quad - 2c_T T_{23} (w'_b + w'_s)[H'][H'_L] + T_{23} (w'_b + w'_s)[H'][H'_L] \right) \, dx_e
\end{align*}
\]
\[
[K_{w_s u}] = b \int_0^{l_e} T_{11} w_s^e[H'][H'_e] dx_e + b \int_0^{l_e} T_{12} (w_b^e + w_s^e)[H'][H'_e] dx_e
\]
\[
[K_{w_s v}] = b \int_0^{l_e} T_{12} w_s^e[H'][H'_e] dx_e + b \int_0^{l_e} T_{22} (w_b^e + w_s^e)[H'][H'_e] dx_e
\]
\[
[K_{w_s w_b}] = b \int_0^{l_e} \left( -c_1 \frac{T_{51}}{2} w_b^e[H'][H'] - T_{13} w_s^e[H'][H'''] - \frac{T_{11}}{2} (w_s^e w_b^e)'[H'] \right) dx_e
\]
\[
\begin{align*}
&+ T_{23} (w_b^e + w_s^e)[H'][H'''] + \frac{T_{21}}{2} (w_b^e + w_s^e) w_b^e[H'][H'] \\
&- c_1 T_{23} (w_b^e + w_s^e)[H'][H'''] + \frac{T_{21}}{2} (w_b^e + w_s^e) w_b^e[H'][H'] \right) dx_e
\end{align*}
\]
\[
[K_{w_s w_s}] = b \int_0^{l_e} \left( -c_1 T_{52} (w_b^e + w_s^e)[H'][H'_e] - 2T_{14} w_s^e[H'][H'_e] + T_{12} w_b^e (w_b^e + w_s^e)[H'][H'_e] \\
- 2T_{24} (w_b^e + w_s^e)[H'][H'_e] + T_{22} (w_b^e + w_s^e)[H'][H'_e] \right) dx_e
\]
\[
[K_{w_s w_b}] = b \int_0^{l_e} \left( -c_1 T_{52} (w_b^e + w_s^e)[H'][H'_e] - 2T_{16} w_s^e[H'][H'_e] + T_{12} w_b^e (w_b^e + w_s^e)[H'][H'_e] \\
- 2c_1 T_{26} (w_b^e + w_s^e)[H'][H'_e] + T_{22} (w_b^e + w_s^e)[H'][H'_e] \right) dx_e
\]
\[
[K_{w_s x}] = b \int_0^{l_e} (T_{21} (w_b^e + w_s^e)[H_e][H'_{e}]) dx_e
\]
\[
[K_{w_s y}] = b \int_0^{l_e} (T_{22} (w_b^e + w_s^e)[H_e][H'_{e}]) dx_e
\]
\[
[K_{w_s w_b}] = b \int_0^{l_e} \left( -2 \frac{T_{41}}{2} w_b^e[H'_e] [H'] - T_{25} (w_b^e + w_s^e)[H_e][H'''] + \frac{T_{21}}{2} (w_b^e + w_s^e) w_b^e[H_e][H'''] \right) dx_e
\]
\[
[K_{w_s w_s}] = b \int_0^{l_e} \left( -2 \frac{T_{41}}{2} w_s^e[H'_e][H'] - c_1 T_{25} (w_b^e + w_s^e)[H_e][H'''] + \frac{T_{21}}{2} (w_b^e + w_s^e) w_b^e[H_e][H'''] \right) dx_e
\]
\[ [K_{w_0}w_b] = b \int_0^{l_e} \left( -2T_{42}(w'_b + w'_s)[H'_L][H_L] - 2T_{24}(w'_b + w'_s)[H'_L][H_L] + T_{22}(w'_b + w'_s)^2[H'_L][H_L] \right) dx_e \]

\[ [K_{w_0}w_0] = b \int_0^{l_e} \left( -2T_{42}(w'_b + w'_s)[H'_L][H_L] - 2c_1T_{42}(w'_b + w'_s)[H'_L][H_L] \right. \\
\left. + T_{22}(w'_b + w'_s)^2[H'_L][H_L] \right) dx_e \]

\[ [K_{w_0}w_s] = b \int_0^{l_e} \left( T_{21}(w'_b + w'_s)[H'_L][H_L] \right) dx_e \]

\[ [K_{w_0}w_s] = b \int_0^{l_e} \left( T_{22}(w'_b + w'_s)[H'_L][H_L] \right) dx_e \]

\[ [K_{w_0}w_s] = b \int_0^{l_e} \left( -2c_1 \frac{T_{61}}{2} w'_b[H'_L][H'] - T_{23}(w'_b + w'_s)[H'_L][H''] + \frac{T_{21}}{2}(w'_b + w'_s)w'_b[H'_L][H'''] \right) dx_e \]

\[ [K_{w_0}w_s] = b \int_0^{l_e} \left( -2c_1 \frac{T_{61}}{2} w'_s[H'_L][H'] - c_1T_{62}(w'_b + w'_s)[H'_L][H'''] \right. \\
\left. + \frac{T_{21}}{2}(w'_b + w'_s)w'_s[H'_L][H'''] \right) dx_e \]

\[ [K_{w_0}w_b] = b \int_0^{l_e} \left( -2c_1 T_{62}(w'_b + w'_s)[H'_L][H_L] - 2T_{24}(w'_b + w'_s)[H'_L][H_L] \right. \\
\left. + T_{22}(w'_b + w'_s)^2[H'_L][H_L] \right) dx_e \]

where \( c_1 = \frac{4}{3h^2} \)

### 3.4 Elemental Stiffness matrix for Cylindrical Bending

The expression for elemental stiffness matrix for cylindrical bending is derived following a procedure similar to the one used for the element stiffness matrix for the HSDT. The number of dependent variables is two and they are \( u \) and \( w \). The \( C^0 \) continuity is used for \( u \) variable whereas variable \( w \) follows \( C^1 \) continuity. The element has 12 degrees of freedom. The stiffness
matrix is subdivided into four submatrices. The stiffness submatrix \([K_{uu}]\) is the only linear part whereas the other three submatrices contain nonlinear terms.

\[
[K_e] = \begin{bmatrix} [K_{uu}] & [K_{uw}] \\ [K_{wu}] & [K_{ww}] \end{bmatrix}
\] (3.17)

Where

\[
[K_{uu}] = b \int_0^{l_e} A_{11} \{H'_L[|H'|] \} dx_e
\]

\[
[K_{uw}] = b \int_0^{l_e} \frac{1}{2} A_{11} w'[H'_L[|H'|] \} dx_e - b \int_0^{l_e} B_{11} \{H'_L[|H'']\} dx_e
\]

\[
[K_{wu}] = b \int_0^{l_e} A_{11} w'[H'][H'_L] dx_e - b \int_0^{l_e} B_{11} \{H'\}[|H'|] dx_e
\]

\[
[K_{ww}] = b \int_0^{l_e} \frac{1}{2} A_{11} (w')^2[H'[|H'|] dx_e - b \int_0^{l_e} B_{11} w'[H'][|H'|] dx_e - b \int_0^{l_e} \frac{1}{2} B_{11} w'[H'']|H'| dx_e
\]

\[
+ b \int_0^{l_e} D_{11} \{H''\}|H''| dx_e
\]

3.5 Finite element Equation

The elemental stiffness matrix \([K_e]\) derived in the previous section is for the individual elements. The elemental stiffness for all the elements are assembled to form the global stiffness matrix \([K(q)]\). The global finite element equations are:

\[
[K(q)]\{q\} = \{Q\}
\] (3.19)

where \([K(q)]\) is the global stiffness matrix. It has both linear and nonlinear stiffness matrices. Thus, global stiffness matrix is a function of \(q\), \(\{q\}\) is the degrees of freedom vector and \(\{Q\}\) is the load vector. The expression for elemental load vector is as follows

\[
Q_e = \int_0^{l_e} p_z \{H(x_e)\} dx_e
\] (3.20)

In natural coordinates,
\[ Q_e = \int_{-1}^{+1} p_z \{H(\xi)\} \frac{l_e}{2} d\xi \]  
(3.21)

Where the \( H(\xi) \) represent shape functions and \( p_z \) is the distributed load. Depending on the variable, the shape functions can be either Hermite or Lagrange polynomials.

The nonlinear finite element equations are solved using the Newton-Raphson iterative process. The size of global stiffness matrix is 112 x 112, the global degrees of freedom vector is 112 x 1 and global load vector is 112 x 1.

### 3.6 NUMERICAL METHODS

#### 3.6.1 Gaussian Quadrature

The numerical method employed in this research for spatial integration is the Gaussian Quadrature. This technique is used for computing both the linear and nonlinear element stiffness matrices as they involve spatial integration. The integration scheme is represented in the following way

\[ \int_{-1}^{1} f(\xi) d\xi = \sum_{i=1}^{m} w_i f(a_i) \]  
(3.22)

where \( m \) is the number of sampling points, \( a_i \) represent the natural coordinate \( \xi \) at the sampling points and \( w_i \) are the corresponding weights.

For a polynomial of order \((2m-1)\), the Gauss quadrature requires \( m \) sampling points to perform exact integration. In the present work, highest order of polynomial is fourteen. Thus, seven sampling points are required. They are listed below, along with their respective weights.

3.6.2 Newton-Raphson Iterative Method

In general, nonlinear finite element equations are solved using an incremental formulation in which the variables are updated incrementally with corresponding successive load steps to trace the path of the solution [Reddy (1997)], [Bathe and Cimento (1980), Felippa (1976), Bathe, Ramm and Wilson (1973), Bathe (1976, 1977, 1979)]. In the iterative method, the nonlinear equations are linearized by evaluating the nonlinear terms with a known solution. In this approach it is important that the governing finite element equations are satisfied in each load step. The accuracy of the solution depends on the size of the load step. To attain accurate result, a small load step need to be taken, thus making the analysis expensive and time consuming. To overcome this problem, an iterative method should be chosen in such a way that larger load steps assure the accuracy of the solutions. The Newton-Raphson method, based on Taylor’s series expansion serves the need. This method is based on the tangent stiffness matrix, which is symmetric for all structural problems though direct stiffness matrix, \([K]\), is not symmetric. Also, this method has faster convergence for most applications than the direct iteration method. Suppose that the solution at \(r^{th}\) iteration, \(\{q\}^r\), is known.

Let

\[
\{R\} \equiv [K]\{q\} - \{Q\} = 0
\]  

(3.23)

Where \(\{R\}\) is called the residual, which is a nonlinear function of the unknown solution \(\{q\}\) and the increment of the solution vector is defined by,

\[
\{\delta q\} = -([K(\{q\}^{r})]^{tan})^{-1}\{R\}^r
\]  

(3.24)

And the total solution at \((r+1)^{th}\) iteration is given by,

\[
\{q\}^{r+1} = \{q\}^r + \{\delta q\}
\]  

(3.25)

The iteration process is continued by solving Eq. (3.24) until a convergence criterion is satisfied.

The error criterion is of the form

\[
\sqrt{\sum_{i=1}^{N} |q_i^{r+1} - q_i^r|^2} < \epsilon \text{ (say } 10^{-3})
\]  

(3.26)

The coefficients of submatrices of element tangent stiffness matrix is defined as follows
\[(K_{ij}^{\alpha\beta})^{tan} \equiv \frac{\partial R_i^\alpha}{\partial q_j^\beta} \equiv K_{ij}^{\alpha\beta} + \tilde{K}_{ij}^{\alpha\beta} \quad (3.27)\]

Where

\[\tilde{K}_{ij}^{\alpha\beta} = \sum_{\gamma=1}^{5} \sum_{l=1}^{n} \frac{\partial K_{il}^{\alpha\gamma}}{\partial q_j^\beta} q_l^\gamma \quad (3.28)\]

The elemental tangential stiffness matrix obtained for HSDT is a symmetrical about its diagonal and is as shown below

\[\begin{bmatrix}
[K_{uu}] & [K_{uy}] & [K_{uw_b}] & [K_{uw_s}] & [K_{uw_b}^\gamma] & [K_{uw_s}^\gamma] \\
[K_{uy}] & [K_{yy}] & [K_{yw_b}] & [K_{yw_s}] & [K_{yw_b}^\gamma] & [K_{yw_s}^\gamma] \\
[K_{uw_b}] & [K_{yw_b}] & [K_{ww_b}b] & [K_{ww_b}s] & [K_{ww_b}b^\gamma] & [K_{ww_b}s^\gamma] \\
[K_{uw_s}] & [K_{yw_s}] & [K_{ww_s}b] & [K_{ww_s}s] & [K_{ww_s}b^\gamma] & [K_{ww_s}s^\gamma] \\
[K_{uw_b}^\gamma] & [K_{uw_s}^\gamma] & [K_{ww_b}^\gamma b] & [K_{ww_s}^\gamma s] & [K_{ww_b}^\gamma b^\gamma] & [K_{ww_s}^\gamma s^\gamma] \\
[K_{uw_s}^\gamma] & [K_{uw_b}^\gamma s] & [K_{ww_s}^\gamma b] & [K_{ww_b}^\gamma s] & [K_{ww_s}^\gamma b^\gamma] & [K_{ww_b}^\gamma s^\gamma]
\end{bmatrix}\quad (3.29)\]

The coefficients of submatrices of element tangential stiffness matrix for HSDT are derived and listed below

3.7 Boundary Conditions

The boundary conditions considered in this research are given below.

3.7.1 Boundary Conditions for HSDT

In the formulation based on HSDT, $\gamma$, $w_b$, $w_s$, $w_b'$, $w_s'$, $w_b^y$ and $w_s^y$ are the end nodal degrees of freedom. The boundary conditions for a pinned end is

$$ u = w_b = w_s = w_b^y = w_s^y = 0 $$

3.7.2 Boundary Conditions for Cylindrical Bending

In the formulation based on Cylindrical Bending, $u$, $w$ and $w'$ are the end nodal degrees of freedom. The boundary conditions for a pinned end is

$$ u = w = 0 $$
4 RESULTS and DISCUSSION

A code is written in MATLAB to solve the nonlinear finite element equations of beam bending based on HSDT using the Newton-Raphson technique. The formulation and the code are verified first by considering a simpler large-deflection problem of cylindrical bending of plates and comparing with existing solutions. The present results for the HSDT case of large deflection are for a pinned-pinned composite beam subjected to positive and negative uniformly-distributed loads; a comparison with the linear case is also made.

4.1 Cylindrical Bending Verification

The MATLAB code incorporating the Newton-Raphson iterative technique for nonlinear analysis is verified by solving the large-deflection problem of cylindrical bending considered by Sun and Chin (1988). The problem consists of a pinned-pinned rectangular composite laminated plate, [0\textdegree/90\textdegree], subjected to a uniform transverse load. The material properties of the graphite-epoxy composite are presented in Table 4.1 as follows

<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Composite</td>
<td>Graphite-epoxy</td>
</tr>
<tr>
<td>$E_1$ (msi)</td>
<td>20</td>
</tr>
<tr>
<td>$E_2$ (msi)</td>
<td>1.4</td>
</tr>
<tr>
<td>$\nu_{12}$</td>
<td>0.3</td>
</tr>
<tr>
<td>$G_{12}$, $G_{13}$, $G_{23}$ (msi)</td>
<td>0.7</td>
</tr>
</tbody>
</table>

The geometric properties of the composite beam are tabulated in Table 4.2

<table>
<thead>
<tr>
<th>Property</th>

</tbody>
</table>

The composite laminated pinned-pinned beam is discretized into four elements with three internal nodes each. The beam is subjected to an axial load of 1 lb/in. The Newton-Raphson iterative method is employed to find out the deflection as the function of position of beam. Figure 4.1 shows the out-of-plane non-dimensional deflection ($w/h$) along the non-dimensional length of beam ($x/L$) when subjected to the axial load of 1 lb/in.
Fig. 4.1 Out-of-plane deflection of [0°/90°] laminate subjected to uniform in-plane load $N_x=1 \text{ lb/in}$

The comparison indicates that the present result agrees well with that of Sun and Chin (1988). The maximum normalized transverse deflection for $N_x=1 \text{ lb/in}$ is 0.006587.

Fig. 4.2 Load-deflection curve of a pinned-pinned composite beam under transverse load
The second verification case pertains to a pinned-pinned beam with the same material and geometric properties and the same lay up as before but the loading is a uniform transverse load. Figure 4.2 shows the plot of the normalized maximum deflection ($w_0/h$) as a function of the load intensity. The graph is plotted for the load varying from 0 to 0.1 lb/in.$^2$. Table 4.2 presents the comparison between the analytical results of Reddy (1997) and the present work. The results show that the agreement between the two sets of results is excellent.

4.2 HSDT Result

The present result is for a [90$_8$/0$_8$] pinned-pinned beam based on the HSDT formulation subjected to a uniformly-distributed load. The material and geometric properties are given in Tables 4.4 and 4.5, respectively. Figure 4.3 shows the plot of the maximum deflection as a function of the transverse load for the range of -0.007 N/mm to +0.03 N/mm. The results are presented in Table 4.6 also. For the sake of comparison, the linear solution is also presented in Fig. 4.3 and Table 4.6. It can be seen that the nonlinear solution varies considerably from that of the linear solution; at the load value of 0.03 N/mm, the nonlinear deflection is less by 42%.

</table>
4.3 Accomplishments and Conclusions

- Successfully formulated the large deflection bending of a composite beam based on HSDT.
- Derived the nonlinear part of the element stiffness matrix based on an h-p version finite element method.
- Derived the tangential stiffness matrix for use in the Newton-Raphson iterative technique.
- Verified the MATLAB code by considering examples of large-deflection of simple cylindrical bending of composite plates.
- It is seen that the nonlinear deflection varies considerably from that of the linear solution and this could play a crucial part in the design of large-deflection structures.

4.4 Future Work

- Perform a parametric analysis by considering different lay ups, different fiber-volume fractions, different types of end conditions, and different types of loads.
- Determine the stresses across the thickness of the laminate at critical cross sections; this would make sure one does not artificially consider large values of the applied load (as the other authors have done), while the beam would have long failed.
- Perform a dynamic analysis.
- Apply to practical cases such as a helicopter blade.
